### BUFFER MANAGEMENT ARCHITECTURE

#### CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to U.S.

Provisional Application Serial No. 60/468,004, filed on May
5, 2003.

#### BACKGROUND

[0002] Switches may be used in a computer network to create a network among a plurality of end nodes (e.g., workstations). A switch includes a number of ports, each of which may be connected to an end node or another switch in the network. The switch channels incoming data from an input port to the specific output port that will take the data toward its intended destination.

[0003] The switch may temporarily store received data (e.g., in the form of packets) in a buffer memory while the switch determines how, when, and through which port to retransmit the packets. Once a packet has been transmitted to its destination, the packet can be cleared from the memory. Since the buffer memory can only buffer a finite number of packets, the switch may include a buffer management module to manage buffers in the buffer memory.

Customer No. 23624 1
Express Mail Label No. EV 398159154 US

#### SUMMARY

A network switch may include a buffer management [0004] module to manage buffers in a buffer memory. The buffer management module may include an Allocation SRAM and a Reclaim SRAM. Each buffer in the buffer memory may be associated with a corresponding data element, e.g., a bit, in the Allocation SRAM and Reclaim SRAM. A line including bits indicating available buffers in the Allocation SRAM may be written to allocation register, and the buffer management module may allocate buffers from the allocation register in response to allocation requests. The buffer management module may identify bits in the allocation register having a value corresponding to an available buffer, change the value of the bit to a value corresponding to an allocated buffer, and allocate the buffer associated with the bit. The buffer management module may clear buffers in response to clear requests by identifying the bit in the allocation register or Allocation SRAM (and Reclaim SRAM), and changing the value of the bit to the value corresponding to an available buffer. If the bit is in the SRAMs rather than the allocation register, the buffer management module may write the line including the bit to a clear map bit register and clear the bit there. The buffer management module may

Customer No. 23624 2 Express Mail Label No. EV 398159154 US monitor the lines in the Allocation SRAM for available lines, i.e., lines including at least one available buffer. When the all of the buffers in the line in the allocation register are allocated, the buffer management module may write the next available line into the allocation register, and allocate buffers from the new line.

A reclaim module may age bits in the Reclaim SRAM. The reclaim module may reclaim buffers by searching corresponding lines in the Allocation SRAM and Reclaim SRAM and comparing the values of bits in the two lines. reclaim module may search the bits in the Reclaim SRAM, identify one or more buffers to reclaim, set the value of the bit associated with the buffer to the value corresponding to an available buffer, and in a subsequent search, compare the bits in the Allocation SRAM to the associated bits in the Reclaim SRAM. The reclaim module may change the value of an bits in the Allocation SRAM with a value corresponding to an allocated buffer to the value corresponding to an available buffer in response to the associated bit in the Reclaim SRAM having the value corresponding to an available buffer.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Customer No. 23624 3 Express Mail Label No. EV 398159154 US [0006] Figure 1 is a block diagram of a network switch including a buffer management module.

[0007] Figure 2 is a block diagram of the buffer management module.

[0008] Figure 3 illustrates the states in a buffer management state machine in the buffer management module.

[0009] Figure 4 is a block diagram of a line indication module in the buffer management module.

[0010] Figure 5 is a block diagram of an allocation section of the buffer management module.

### DETAILED DESCRIPTION

[0011] Figure 1 is a block diagram of a network switch 100 according to an embodiment. The switch includes a number of ports 102, each of which may be connected to an end node (e.g., a workstation) or another switch in a computer network.

[0012] The switch 100 may include a switching module 104 to switch/route received packets. When a packet is received, the switching module may build a descriptor from header data in the packet and store the packet in a buffer memory 106. The buffer memory 106 may include contiguous buffers, each large enough to store a packet of a given size a portion of a packet. A buffer management module 108

Customer No. 23624 4
Express Mail Label No. EV 398159154 US

manages buffers in the memory to ensure that buffers are available for incoming packets.

Figure 2 is a block diagram of a buffer management module 108 according to an embodiment. The buffer management module 108 supplies (allocates) available buffers in the buffer memory 106 in response to buffer requests and clears allocated buffers in response to clear requests. The buffer memory 106 may buffer short and long packets. Packet types (short/long) may be assigned to the ports. The buffer management module 108 may allocate (and clear) short and long packets in a similar manner. buffer management module 108 may provide a reclaim mechanism to reclaim buffers that may become stuck in the system (i.e., fail to release) due to some malfunction. For example, data may not be transmitted if there are some errors in the network, such as a port being broken or a switch connected to a port being removed from the network. In either case, the buffers associated with those ports need to be cleared or else the associated buffers will become stuck.

[0014] The buffer management module 108 may include an Allocation SRAM 202 and a Reclaim SRAM 203. In an embodiment, the SRAMs are 128x128 SRAMs (16kbits). Each buffer in the buffer memory 106 is associated with a bit in

Customer No. 23624 5
Express Mail Label No. EV 398159154 US

the Allocation SRAM 202. The number of available buffers in the buffer memory 106 may be smaller than the number of available bits in the Allocation SRAM 202. In that case, a number of lines in the Allocation SRAM 202 and Reclaim SRAM 203 may be masked off. A translation module may perform a translation between bit numbers in the Allocation SRAM 202 and the corresponding addresses of buffer locations in the buffer memory 106. The following description may refer to bit numbers in the Allocation SRAM 202 and the corresponding locations where the packets are buffered in the buffer memory 106 as "buffers".

[0015] One of the lines from the Allocation SRAM 202 may be stored in an allocation register 204 (e.g., a 128-bit register for the 128x128 Allocation SRAM 202) at a time. Buffers may be taken from empty spaces (bit=0) in the line currently in the allocation register 204 in response to buffer requests (buff\_req\_). When allocated, the value of the bit may be set to "1", indicating a full buffer. A "rd\_pointer" signal identifies which line from the Allocation SRAM 202 is in the allocation register 204.

[0016] The allocation register 204 may include separate long and short allocation registers for the allocation of

Customer No. 23624 6
Express Mail Label No. EV 398159154 US

long and short packets, respectively.

[0017] The buffer management module 108 may include a buffer management state machine (BMSM) 200. The BMSM 200 may control which module in the buffer management module 108 has access to the Allocation SRAM 202 and/or Reclaim SRAM 203 and/or allocation register 204 (for clearing buffers from the long/short allocation registers). Figure 3 illustrates the branches in the BMSM 200 and corresponding states the BMSM 200 may transition between. The buffer management module 108 may include a short allocation branch 302, a long allocation branch 304, a clear branch 306, and a reclaim branch 308.

[0018] An allocation arbiter 206 handles buffer requests from clients. The allocation arbiter 206 may be a first-come-first-serve (FCFS) arbiter. The allocation arbiter 206 decides which requests are to be forwarded to an allocation state machine (Alloc\_SM) 208. The Alloc\_SM 208 may supply the next empty buffer in the line currently in the allocation register 204. The allocation of the buffers may be done in a "forward" manner, e.g., from buffer number 0 to the last available buffer. A buffer that was cleared from the allocation register may be reallocated again. The allocation/clear from the allocation registers may be done in the same cycle in parallel.

Customer No. 23624 7
Express Mail Label No. EV 398159154 US

[0019] When the line in the allocation register 204 is full (i.e., all bits=1), the BMSM 200 issues a control signal to write the full line in the allocation register 204 to the Allocation SRAM 202 and to the corresponding line in the Reclaim SRAM 203 (state "WR\_ALLOC\_REG" 310 in Figure 3). The next available line in the Allocation SRAM 202 (i.e., a line including at least one empty buffer) is identified and written to the allocation register 204. The rd\_pointer is updated to the address of the new line ("WR\_RD\_POINTER" 312). New buffers may then be allocated from the new line in the allocation register 204 ("RD NEXT REG" 314).

[0020] Allocation counters 210 may be used to count the number of allocated buffers. The allocation counters 210 may be used to indicate when there are no more buffers available. A maximum number of buffers may be allocated for a particular port to prevent other ports from being starved. The allocation counters 210 may also be used to count the number of allocated buffers per port and indicate to the allocation arbiter 206 when a port has been allocated its maximum number of buffers.

[0021] The next available line (i.e., with at least one empty buffer) in the Allocation SRAM 202 may be determined by a line indication module 212 coupled to the allocation

Customer No. 23624 8
Express Mail Label No. EV 398159154 US

register 204. The next available line is determined through a search of a free line vector generated by the line indication module 212. The free line vector may have a number of bits corresponding to the number of lines in the Allocation SRAM 202 (e.g., 128). Initially, all bits in the free line vector may be set to "0", indicating that all lines include empty buffers. When a line is written to the Allocation SRAM 202 from the allocation register 204 (i.e., when the line is full), a "1" may be written to the bit location in the free line vector corresponding to that line. If a clear operation (described below) is performed on a line in the Allocation SRAM 202 to clear a bit, a "0" may be written to the bit location in the free line vector corresponding to that line. Thus, full lines are indicated by "1" and lines with one or more empty buffers are indicated by "0" in the free line vector. The next available line (with at least one empty buffer) can be determined by searching the free line vector.

[0022] A clear arbiter 214 may handle clear requests (clear\_req\_). The clear arbiter may be an FCFS arbiter. The clear arbiter 214 decides which clear request will be forwarded to the BMSM 200. The BMSM 200 checks to see if the buffer to be cleared is in the allocation register 204 ("CLEAR\_BUS\_LOCK" 320). If so, the buffer is cleared from

Customer No. 23624 9
Express Mail Label No. EV 398159154 US

the allocation register 204, and the BMSM 200 returns to an idle state 300. However, if the buffer to be cleared is not in the allocation register 204, the line containing the buffer is read from the Allocation SRAM 202 into a clear map bit register 216 and the corresponding line in the Reclaim SRAM 203 is read into a reclaim clear map bit register 218 ("READ\_CLEAR" 322). The bit is then cleared in both registers ("CLEAR\_BIT" 324) and the line is rewritten to the Allocation SRAM 202 and Reclaim SRAM 203 ("WRITE\_CLEAR" 326). A multiplexer 250 controls access to the Allocation SRAM 202 from the allocation register 204 and the clear map bit register 203.

[0023] If the specific buffer subject to the clear request was not allocated, or already cleared by the reclaim mechanism, a signal is transmitted to the allocation counters 210 to prevent them from being decremented. There may also be an interrupt indicating that a malfunction occurred.

[0024] The reclaim module 220 may operate in two modes: a trigger mode and an automatic mode. A reclaim trigger may be issued periodically or when needed. In response to the reclaim trigger, the entire Allocation SRAM 202 is searched in one pass, and any full buffers in the

Allocation SRAM 202 are written to the corresponding bit locations in the Reclaim SRAM 203.

In the automatic mode, the lines in the Reclaim [0025] SRAM 203 may be searched continuously in a loop fashion (i.e., from line 0 to the last unmasked line and back to line 0). A configurable timer may be used to set the time between searching between lines. The reclaim module 220 reads a line from the Allocation SRAM 202 and from the Reclaim SRAM 203 ("READ\_RECLAIM" 330). The reclaim module 220 then waits for the data from the Allocation SRAM 202 and from the Reclaim SRAM 203 ("WAIT READ RECLAIM" 332). The reclaim module 220 compares the line in the Reclaim SRAM 203 to the corresponding line in the Allocation SRAM 202, and calculates an aging vector ("WAIT\_AGING\_VECTOR" 334). The reclaim module 220 may set bits in the aging vector corresponding to buffers that should be aged to "0". The reclaim module 220 writes the line back to the Reclaim SRAM 203 ("WRITE RECLAIM" 336).

[0026] In subsequent searches in the trigger mode, the lines in the Allocation SRAM 202 and the Reclaim SRAM 203 are compared. As described above, when a new line is written back from the allocation register 204 to the Allocation SRAM 202 (a full line), it is also written to the Reclaim SRAM 203. Also, if a buffer is cleared from the

Customer No. 23624 11
Express Mail Label No. EV 398159154 US

Allocation SRAM 202, it is also cleared from the Reclaim SRAM 203. During the search in a line in the Reclaim SRAM 203, a buffer is set (= "1"), will be reset (= "0"). In the next pass, when the same line is searched again, if a bit corresponding to a buffer is set (= "1") in the Allocation SRAM 202 and the corresponding bit in the Reclaim SRAM 203 is reset (= "0"), the buffer is cleared by resetting the bit in the Allocation SRAM 202 to "0", freeing that buffer to be allocated. This may prevent buffers from becoming stuck in the system. Also, the counter are decremented by the number of cleared buffers.

[0027] In both the trigger mode and the automatic mode, the line in the Allocation SRAM 202 (and Reclaim SRAM 203) currently in the allocation register 204 is skipped during the search through the SRAMs. This may prevent recently allocated buffers from being mistakenly cleared.

[0028] Figure 4 is a block diagram of a line indicator module according to an embodiment. The line indicator module may include a line mask module 402, a free line vector module 404, an OR gate 410, and a next free line module 406.

[0029] The number of available buffers in the buffer memory 106 may be smaller than the number of available bits in the Allocation SRAM 202. In that case, a number of

Customer No. 23624 12 Express Mail Label No. EV 398159154 US lines in the Allocation SRAM 202 may be masked off by a "line\_ind\_mask" signal generated by the line mask module 402 based on a "local max line space" input.

[0030] The main inputs to the free line vector module are "line\_ind" and "rd\_pointer". The line\_ind input represents the entire possible allocation space, including the masked lines. The rd\_pointer input is the address of the line in the allocation register 204 and provides the starting pointer for the search for the next empty line. The free line vector module 404 operates on the line\_ind input to generate the 128-bit free line vector used to determine the next available line.

[0031] When a full line from the allocation register 204 is written back to the Allocation SRAM 202, the BMSM 200 generates a "load\_line\_ind\_alloc\_" control signal, which indicates that the particular line is full. The free line vector module 404 sets the bit corresponding to the full line to "1". If a buffer is cleared by the BMSM 200 (in response a clear command), a "load\_line\_ind\_clear\_" control signal sets the bit corresponding to the line containing the buffer to "0".

[0032] If a buffer is aged by the reclaim mechanism, the "load\_line\_ind\_reclaim\_" control signal sets the bit corresponding to the line containing the buffer to "0".

Customer No. 23624 13 Express Mail Label No. EV 398159154 US This line is identified by a "reclaim2alloc\_map\_addr" signal.

[0033] Figure 5 is a block diagram of an allocation section according to an embodiment. A line curr ptr register 502 holds a pointer to the last allocated buffer in the allocation register 204, which is used as a starting point for the search for the next empty buffer in the line. The input to the allocation register 204 is controlled by a multiplexer 550, and the input to the line\_curr\_ptr register 502 is controlled by a multiplexer 552. A rd pointer register 504 holds the pointer to the address of the Allocation SRAM 202 line that is loaded into the allocation register 204. The input to the line\_curr\_ptr register is controlled by a multiplexer 554. The Alloc SM 208 issues a "load\_nxt\_addr\_" control signal when a new buffer should be allocated. This signal locks the buffer pointer to the next empty buffer in the allocation register 204 into a bm\_addr[7:0] 510 register and the rd pointer address into a bm\_addr[15:8] 512, the inputs to which are controlled by multiplexers 556 and 558, respectively. The combined address bm addr[15:0] is the address of the buffer to be allocated.

[0034] After the allocation of a buffer, the allocation register 204 is updated and a new empty buffer is searched.

Customer No. 23624 14
Express Mail Label No. EV 398159154 US

The allocation SM issues a "load\_alloc\_reg\_nxt\_" control signal to lock the updated line in the allocation register 204 and update the line curr ptr register 502.

[0035] When a buffer in the allocation register 204 is to be cleared, the BMSM 200 issues a "load\_alloc\_reg\_cl\_" control signal, and the buffer at the addresses provided on the clear bus (clear\_bus\_arb\_buf\_data) is cleared. An allocation and clear to the allocation register may be done in parallel in the same cycle.

[0036] When the line in the allocation register 204 is full, the BMSM 200 issues a "load\_nxt\_free\_addr\_" control signal. This loads the rd\_pointer register 504 with the nxt\_free\_line signal from the free line vector module 212 (Figure 4). The BMSM 200 issues a "load\_nxt\_free\_line\_" signal to lock the new line in the allocation register 204 and update the line\_curr\_ptr register 502.

[0037] A number of embodiments have been described.

Nevertheless, it will be understood that various modifications may be made without departing from the spirit and scope of the invention. For example, more than one bit may be used to represent the individual buffers. Also, other values may be used to indicate full and empty buffers. Accordingly, other embodiments are within the scope of the following claims.

Customer No. 23624 15 Express Mail Label No. EV 398159154 US
